Introduction

Short peptides are widely used as ligands in affinity chromatography purification of proteins [1,2]. However, peptidases and proteases present in the crude sample may degrade immobilized peptides, shortening the affinity support useful life. Then, peptide ligand stability must be evaluated before its use in a purification process. Commonly, enzymatic stability is evaluated with the peptide in solution, which may differ from the resin-bound peptide behavior [3]. Further, as the peptides to be evaluated are in solution in the reaction mixture, the study of the peptide degradation products requires purification steps before their analysis [4].

In this work we developed a strategy to evaluate immobilized peptide stability using electrospray ionization (ESI) and matrix assisted laser desorption/ionization (MALDI) mass spectrometry (MS).

Results and Discussion

ChemMatrix (CM) was used as the solid support due to its chemical stability. This PEG-based matrix allowed peptide synthesis in organic solvents and stability peptide evaluation in aqueous solvents [5]. 4-Hydroxymethylbenzoic acid (HMBA) [6] was used as the linker in order to introduce a cleavage site to release the peptides from the beads before MS analysis. The model peptide H-Phe-Lys-Phe-Arg-Tyr-Thr-Ala-His-Ser-Gly-Ala-Ser-Gly-NH₂ with known trypsin and chymotrypsin cleavage sites [7] was synthesized on HMBA-CM resin (0.63 mmol/g) by using the Fmoc strategy as we have previously described [1]. Ser-Gly-Ala-Ser-Gly was incorporated as a spacer arm at the C-terminal. After peptide elongation, protecting groups were removed with trifluoroacetic acid (TFA)/triisopropylsilane (TIS) /H₂O (95:2.5:2.5 v/v/v), leaving the unprotected peptides anchored to the resin. Peptide beads were washed with dichloromethane (DCM), N,N-dimethylformamide (DMF), H₂O:DMF (3:7; 5:5; 7:3 v/v)

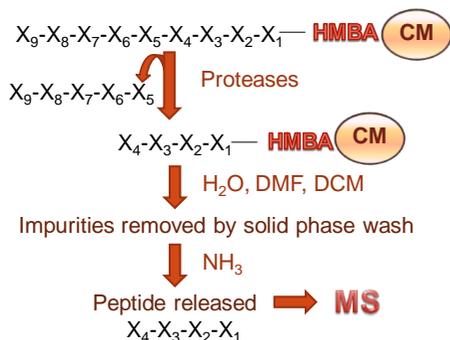

Fig. 1. Strategy for immobilized peptide stability evaluation.

and H₂O. Then, 0.1 mg of peptidyl-resin (approximately 100 peptidyl-beads) was incubated with solution A (trypsin 40 μM in Tris-HCl 40 mM, pH 8.1, CaCl₂ 10 mM buffer) or B (chymotrypsin 40 μM in Tris-HCl 40 mM, pH 8.1, CaCl₂ 10 mM buffer) overnight. The peptidyl-beads were then thoroughly washed with H₂O, H₂O:DMF (7:3; 5:5; 3:7 v/v), DMF and DCM. Later on, peptides were detached with ammonia vapor. Released peptides were eluted by adding acetic acid/acetonitrile (CH₃CN) / H₂O (3:4:3 v/v/v) (Figure 1). Eluted peptides were analyzed by mass spectrometry (MS). ESI mass spectra were recorded in a Bruker microTOF-Q II (Bruker Daltonics GmbH, Leipzig, Germany). 5 μL aliquot of eluted peptide was injected and analyzed in positive mode. MALDI mass spectra were recorded in an Ultraflex II TOF/TOF (Bruker Daltonics GmbH, Leipzig, Germany). 1 μL Aliquot of eluted peptide from 100 beads was loaded onto the sample plate, air-dried at room temperature, and then 1 μL of MALDI matrix solution was added on the sample dry layer (successive-dry-layers deposit method). Two matrices solutions were assayed: a) Commercial E-α-cyano-4-hydroxycinnamic acid (CHCA) 4

mg/mL in CH₃CN/H₂O (1:1 v/v) with 0.1% TFA and b) Z-sinapinic acid (SA) [8,9] 5 mg/mL in MeOH/H₂O (7:3 v/v). Mass spectra were acquired in the MS reflectron positive ion mode.

Figure 2 shows the ESI mass spectra obtained before and after subjecting the peptide-beads with chymotrypsin and trypsin. ESI-MS allowed the detection of the whole peptides (Figure 2 A) as well as their C-terminal enzymatic degradation products (Figures 1 B and C) obtained after incubation with trypsin and chymotrypsin.

When analyzing the peptide and their degradation products with MALDI-MS, E- α -cyano-4-hydroxycinnamic acid matrix clusters interfered in MALDI-MS analysis of low molecular weight products. On the other hand, Z-sinapinic acid matrix allowed their analysis (Figures 1 D and E).

The method here developed allowed a fast evaluation of peptide ligands stability in solid phase towards the proteases that may be present in the crude sample before their use in affinity chromatography. Due to the high sensitive of mass spectrometry, only a small sample of peptidyl-resin is required to evaluate its stability. As the enzymatic degradation is performed in solid-phase, none hard purification protocols are needed before analysis.

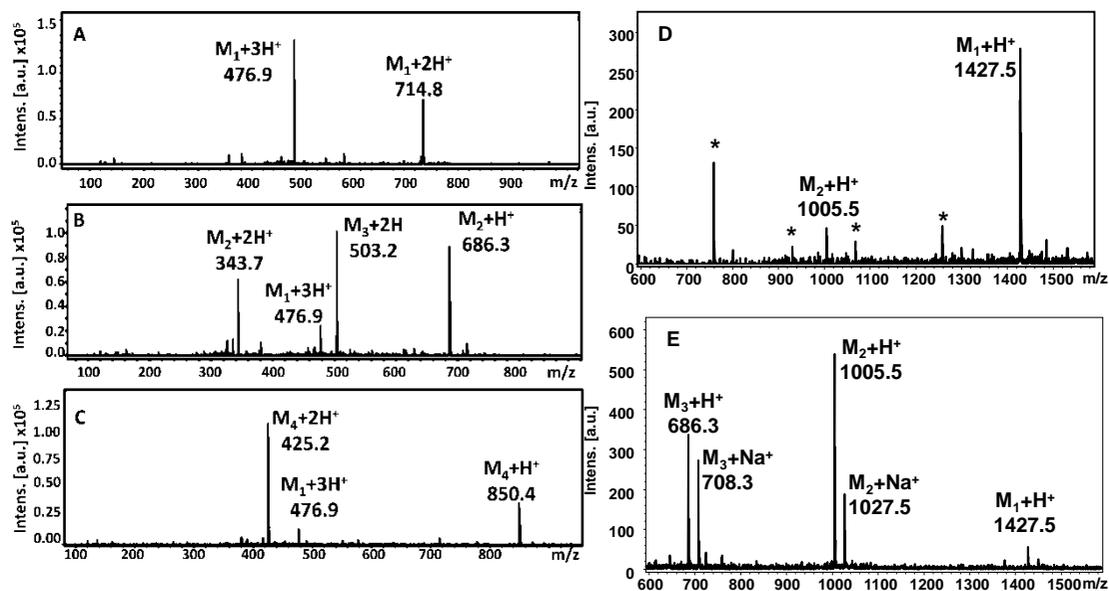

Fig. 2. ESI mass spectra of peptide H-Phe-Lys-Phe-Arg-Tyr-Thr-Ala-His-SerGly-Ala-Ser-Gly-NH₂ before (A) and after treatment with chymotrypsin (B) and trypsin (C). The signals at m/z 476.9 and 714.8 correspond to the whole peptide FKF₁RYTAHSGASG [M₁+3H⁺] and [M₁+2H⁺] respectively. The signals at m/z 343.7 and 686.3 correspond to the degradation product TAHSGASG [M₂+2H⁺] and [M₂+H⁺] respectively and 503.2 correspond to the degradation product RYTAHSGASG [M₃+2H⁺]. The signals at m/z 425.2 and 850.4 correspond to the degradation product YTAHSGASG [M₄+2H⁺] and [M₄+H⁺]. MALDI mass spectra of peptide FKF₁RYTAHSGASG after treatment with chymotrypsin using α -cyano-4-hydroxycinnamic acid matrix (D) or using Z-sinapinic acid matrix (E). The signal at m/z 1427.5 corresponds to the whole peptide FKF₁RYTAHSGASG [M₁+H⁺]. The signals at m/z 1005.5 and 1027.5 correspond to the degradation product RYTAHSGASG [M₂+H⁺] and [M₂+Na⁺] respectively. The signals at m/z 686.3 and 708.3 correspond to the degradation product TAHSGASG [M₃+H⁺] and [M₃+Na⁺] respectively. The signals marked with an asterisk (*) correspond to the matrix matrices clusters.
